This paper is based on the experimental and clinical data gathered by the authors for almost 25 years. They came to a definite conclusion about the phonological structure of Mandarin long vowel verbs. The existence of the short and long radicals in this language and the disyllabic character of these verbs, as shown by the experimental data, allowed them to isolate both radicals, i.e. the long one is an independent radical, which means that it has no connection with the short one. The short radical consists of three morphemes: the "head" consonant, with which the long radical begins, and two vowels. The phonetic process of vowel change is the basis of verb formation. The result of the combination of the long radical and the long vowel is the following syllable pattern: [k] [V] [V]. According to the above, the phonemic structure of Mandarin long vowel verbs is as follows: [k] [V] [V].Trigonelline Trigonelline is the chiral isomer of trigonelline. Phase-change memory (PCM) utilizes phase-change materials, i.e., materials that may be electrically switched between a generally amorphous and a generally crystalline state, for electronic memory application. One type of PCM utilizes a chalcogenide alloy, which may be electrically switched between a structural state of generally

amorphous and generally crystalline local order or between different detectable states of local order across the entire spectrum between completely amorphous and completely crystalline states. The state of the phase-change materials is also non-volatile, meaning that the memory cells of a PCM circuit representing a binary data value (e.g., "0" or "1") remain content until reprogrammed. When programmed, a phase-change material may change states, e.g., from the amorphous state to the crystalline state. A phase-change material may be used for forming a PCM cell including at least a chalcogenide alloy layer, a resistance change material layer formed on the chalcogenide alloy layer, and a top electrode formed on the resistance change material layer. The amorphous state may be marked by a high electrical resistance, while the crystalline state may be marked by a lower electrical resistance. Current

flows through the cell when the chalcogenide material is in the amorphous state and quenched by driving current through the material while heating the material to a range of temperatures generally associated with the crystallization of chalcogenide alloys. Conventionally, PCM memories are erased using pulse write operations to write a block of data, which may be a logical "1" or "0", to the memory. Erasure is performed to reset the PCM memory to the desired programming state.The effect of reducing energy wastage by changing the positioning of emergency enteral feeding tubes during surgical procedures in critically ill patients.
